Recovery of subcutaneous fat depots after prolonged submaximal training. The effects of 10 weeks of submaximal training on total body mass and body composition were studied in 15 healthy men aged 19-27. They were assigned to one of three groups. Each group performed a 10-week program of treadmill running which involved running at a workload of 60-65% of the lactate threshold. The training program involved one daily training session for a total of 50 minutes. The low-intensity exercise increased the training intensity significantly. During the training period of 10 weeks the low-intensity training program caused a significant decrease in body mass and body fat. After the training period the body fat decreased and the lean body mass increased significantly in all three groups. The results suggest that a1d647c40b
